Prepared reports. Faster review. Better operational context.

Printable executive overview of a SharePoint-first manufacturing intelligence platform.

How people use the outputs

Shift Drafts: supervisors receive a prepared starting point, review exceptions, add context, and finalize. **Daily Production:** managers investigate production, molding, labor, quality, plan attainment, and downtime. **Weekly Production + Downtime:** teams identify trends, recurring constraints, and planning priorities.

COLLECT INPUTS	PREPARE REPORTS	REVIEW EXCEPTIONS	TAKE ACTION
People record production activity	Automation assembles a starting point	People verify and add context	Interpret, prioritize, coordinate

Additional initiatives

Delivered extensions: QR/Form machine-event intake, notifications, and a SharePoint dashboard improve operational visibility; a functional read-only Reporting Assistant answers bounded, source-grounded queries with validated citations, diagnostics, evidence checks, and deterministic refusal. Broader model-backed reasoning, document knowledge, recurring artifacts, and production advisory remain future work.

Qualified impact evidence

Core reporting model: 30 hours/week or 1,560 hours/year addressed and about $52K annual labor-capacity value. **Reporting Assistant estimate:** about 90% faster retrieval based on a representative 20-30 minute search versus a 1-2 minute cited response; not a controlled production benchmark. **Machine-visibility upper bound:** up to 227.5K production units and about $205K contribution-margin opportunity.

The value pools are separate and are not added together. Planning models are not realized outcomes. Underlying company-specific assumptions are omitted from this public case study.

People make decisions; the platform provides evidence.
